Abstract

Market concentration and weak competition do not just lead to lower efficiency but also result in corporate profits flowing primarily to wealthy households that own a disproportionate share of public corporations. We demonstrate that this is a growing distributional problem not only due to familiar reasons in the literature, most notably shifts in market power, but also due to changes in the socio-economic makeup of ownership. Over the past twenty years, households in the bottom 90 percent of wealth have seen their share of stock ownership decline by half. That is, the ownership of corporations has become increasingly concentrated among the wealthy at a time when corporations are arguably extracting ever more surplus from consumers and workers. This Article seeks to situate the distribution of ownership at the center of policies to address the impact of declining competition. The gist of our proposal is that policies to reverse existing trends by broadening the ownership of public corporations to middle- and low-income households may help mitigate the harmful consequences of market power. The general objective of such policies would be to bring the distribution of ownership closer towards equal ownership of corporations by the public. Equal ownership is desirable for two main reasons. First, the simplest effect of equal ownership would be to enable a broader array of stakeholders to benefit from the excess profits earned by firms in concentrated markets. Second, we demonstrate theoretically that if corporate stakeholders, particularly consumers and workers, own shares in public corporations, managers may offer more competitive prices and wages, to the extent that managers internalize the interests of their owners. Accordingly, policies to promote equal ownership of corporations can serve as a complimentary policy tool to existing policies, such as antitrust and regulation, and offers potentially consequential advantages.

Abstract. Market concentration and weak competition do not just lead to lower efficiency but also result in corporate profits flowing primarily to wealthy households that own a disproportionate share of public corporations. We demonstrate that this is a growing distributional problem not only due to familiar reasons in the literature, most notably shifts in market power, but also due to changes in the socio-economic makeup of ownership. Over the past twenty years, households in the bottom 90 percent of wealth have seen their share of stock ownership decline by half. That is, the ownership of corporations has become increasingly concentrated among the wealthy at a time when corporations are arguably extracting ever more surplus from consumers and workers.

This Article seeks to situate the distribution of ownership at the center of policies to address the impact of declining competition. The gist of our proposal is that policies to reverse existing trends by broadening the ownership of public corporations to middle- and low-income households may help mitigate the harmful consequences of market power. The general objective of such policies would be to bring the distribution of ownership closer towards *equal ownership* of corporations by the public.

Equal ownership is desirable for two main reasons. First, the simplest effect of equal ownership would be to enable a broader array of stakeholders to benefit from the excess profits earned by firms in concentrated markets. Second, we demonstrate theoretically that if corporate stakeholders, particularly consumers and workers, own shares in public corporations, managers may offer more competitive prices and wages, to the extent that managers internalize the interests of their owners. Accordingly, policies to promote equal ownership of corporations can serve as a complimentary policy tool to existing policies, such as antitrust and regulation, and offers potentially consequential advantages.

INTRODUCTION

The recent decades have seen a dramatic rise in corporate profits.[1] The ability to extract these ever-higher profits is due, in large part, to a steady increase in market concentration across many industries.[2] But while this increase in corporate profits has greatly benefitted investors, there is evidence that it has left out most consumers and workers. Average consumer product prices have increased over time, arguably due to limited competition.[3] Hourly wages to workers have remained largely stagnant, despite workers' increasing productivity, again because large profitable firms may wield enormous market power in labor markets.[4] The literature has devoted considerable attention to how market power has increasingly harmed non-wealthy consumers and workers[5] and benefited wealthy households that own a disproportionate share of public corporations.[6]

We argue that this is a growing distributional problem not only due to familiar reasons in the literature—most notably shifts in market power away from consumers and workers—but also due to changes to the socio-economic makeup of ownership. As shown in Figure 1, while market power and income inequality rose steadily through recent decades,[7] another concerning trend went largely overlooked. Since 2000, the bottom 90 percent of households, or those with

incomes below $180,000, have seen their share of ownership of public corporations decline from around 22 percent to 11 percent.[8] Consequently, the people who bear most of the burden of rising prices and stagnant wages have, over time, also received a smaller share of the resulting profits.[9]

We argue that expanding the ownership of corporations to all households has the potential to mitigate the harmful consequences of excess market power on consumers and workers. Although we cannot systematically determine the optimal allocation of ownership, we use the term *equal ownership* to denote the general aspiration that a broader array of stakeholders, particularly consumers and workers, will have a sizeable and influential ownership stake in capital markets. While some form of this idea has floated amorphously in various policy proposals,[10] we are the first to theorize equal ownership across socio-economic groups as a

[9] We do not claim that these trends are necessarily related, but it is possible that they are. In particular, when wages are stagnant and prices go up, lower-income individuals likely have less money to save and invest in the stock market. It is also possible that, as we discuss below in Section II.C. when owners are wealthier, corporations are less likely to internalize the interests of consumers and workers because wealthier owners are less likely to be affected by higher prices and lower wages.

[10] For ideas about expanding ownership that do not explore the link to market power, see MICHAEL SHERRADEN, ASSETS AND THE POOR: A NEW AMERICAN WELFARE POLICY 220–23 (1991); LYNN STOUT, SERGIO GRAMITTO & TAMARA BELINFANTI, CITIZEN CAPITALISM: HOW A UNIVERSAL FUND CAN PROVIDE INFLUENCE AND INCOME TO ALL 119–24 (2019); Robert Hockett, *Whose Ownership? solution to corporations' excessive market power and their ability to extract rents from consumers and workers.

The basic intuition for our theory has two components: First, if consumers, workers, and the public have a larger ownership stake, as owners they will share in the economic gains made by corporations. Consequently, when corporations raise prices or decrease wages, at least consumers and workers would get back some of those losses through their ownership stake in the resulting increased profits. Equal ownership could thus allow more stakeholders to share in the rents of market power to the extent that they get a larger share of corporate profits. Second, to the extent that managers are accountable to owners or at least assimilate their preferences, equal ownership could mitigate managers' incentives to exploit their market power to extract rents from their stakeholders. Accordingly, corporations with a broader set of owners that include average consumers and workers would plausibly charge fairer prices and pay higher wages.[11]

Our insight suggests that, at least theoretically, equal ownership may be able to move markets toward outcomes that mimic those in a world of perfect competition. While it is widely recognized that markets realistically never reach perfect competition, it provides a normative benchmark for policymakers.[12] In the classic and highly stylized model of perfect competition, consumers and workers extract all the surplus from market transactions with commercial firms.[13] This idea of perfect competition is largely based on the presence of numerous competitors,[14] without considering the attributes of owners. We show that in well-known economic models, when the owners are also the consumers of the firm, the firm is likely to charge consumers the same price it would in a market with perfect competition (and the same applies to workers and wages).[15] If similar outcomes could be obtained by changing the composition of owners, the goal post for economic policies should arguably be not only traditional mechanisms for moving markets towards perfect competition, such as antitrust and consumer protection, but also the promotion of equal ownership by a broader section of the public that includes middle- and low-income consumers and workers.

Although our main contribution is to expand the theoretical justification for broadening ownership, we also discuss specific policies to implement equal ownership. We consider a

range of paths to expanding ownership, such as tax incentives or repurposing a portion of Social Security. The success of such policies should be gauged not by whether they achieve a seemingly unrealistic equal distribution of ownership of public corporations. Rather, the more immediate goal is to reverse the concerning state in which an increasingly smaller share of public firms is held by less wealthy individuals.

Although reversing that concerning ownership trend is valuable by itself, there is no guarantee that broader ownership by itself will produce changes in corporate decision-making on issues such as prices and wages. Thus, we discuss an array of institutional mechanisms to promote managerial responsiveness to the interests of a broader set of owners, such as information technologies that could vote directly on shareholders' behalf after asking for their preferences or alternatively communicate such preferences to fund managers who will have a fiduciary duty to consider them in making voting decisions or engaging with corporate managers.[16]

In this respect, our project is tangentially related to a burgeoning literature on common ownership of corporations that creates a link between corporate governance and market competition. The main concern in the common ownership literature is that firms that are owned by the same set of large institutional shareholders, such as BlackRock and Vanguard, are less likely to compete with one another and will thus charge higher prices to consumers[17] or pay lower wages to workers.[18] An underlying premise in those arguments is that managers internalize the interests of institutional shareholders and thus maximize the aggregate value of their owners' portfolios by failing to compete with other commonly owned firms.[19] There is a heated debate as to whether seemingly passive institutions can actually affect managerial decisions-making,[20] and we do not take a stance on this issue. For our purposes, the upshot of the common ownership literature is that it suggests that it is plausible that managers do consider owners' interests in making decisions, even if the extent to which they do so is debatable. And in any case, even if shareholders' preferences are not adequately accounted for, equal ownership would still offer policy appeal by providing a mechanism to distribute the rents of corporate profits to less affluent households.

It bears emphasis that common ownership and equal ownership are focused on institutionally distinct but complementary problems. They are complementary in that both ultimately indicate policy reforms that would push markets toward more competitive prices

To the extent that wealthier individuals hold stocks through institutions, a highly reasonable presumption, then the potentially harmful effect of common ownership further exacerbates the distributional problem that is at the center of this Article.

and wages. However, even if the proposals in the common ownership literature are successful in preventing institutions such as Vanguard from having concentrated ownership of competitors, those reforms would neither change the socio-economic makeup of owners nor affect the problem of market concentration.[21] The same mostly wealthy households would still hold the same proportion of corporations in a world without common ownership, only through a more fragmented institutional landscape. In contrast, equal ownership is not concerned with a more fragmented distribution of institutions that hold shares. Equal ownership aims instead to broaden the socio-economic distribution of individuals (or households) who own corporations (directly or through institutions).

Policies to promote equal ownership have some advantages over many other proposals seeking to address corporations' market power. Existing proposals, in one way or another, face the daunting challenge of undermining the normative objective that corporate law seeks to accomplish: inducing business organizations to maximize owners' profits. Interventions based in antitrust and market regulation, for instance, impose the dictates of regulators or courts over owners' interests in making profits to determine how managers should run the business. This tension helps explain why such proposals are often risky and costly.[22] Relatedly, another line of proposals advocates a change to the basic objective of corporations; rather than maximizing shareholder profits, boards should maximize the benefits to all stakeholders, including consumers and workers.[23] Those proposals push against the basic incentive structure of corporations, in which managers are primarily accountable to the owner-shareholders, either though elections (for boards) or through performance-based pay (for executives).[24]

We do not pass judgment on these other proposals' social value. Nor is it possible at this point to conclude that any one proposal is necessarily the best of all possible policy options. Such a difficult comparison would require nuanced institutional comparisons informed by experimentation with interventions, such as equal ownership, that have never been tried. But as a threshold observation for those institutional comparisons, a key advantage of equal ownership is that it does not fight against the basic architecture of corporations, which is that managers have to a duty to maximize shareholders' interests.[25] These interests are not necessarily confined to making larger profits but could also include shareholders' interests in being treated fairly as consumers and workers,[26] or at least getting a larger share of corporate

profits.

Finally, we emphasize that other mechanisms for addressing market power, such as antitrust and regulation, would still have a central place in a world of equal ownership. However, given the imperfections of standard policy responses to declining competition, equal ownership could serve as a complementary policy tool to existing approaches, and it offers potentially compelling advantages. Equal ownership is rooted deeply in the link between corporate ownership and competitive markets. The nature of ownership shapes the way firms compete in the product and labor markets. Policymakers would be ill-advised to ignore this link. Even if equal ownership would fall short at eliminating market power altogether, at a minimum it will move society away from the trend toward tapered ownership.

Our Article proceeds as follows. Part I provides the context for equal ownership by outlining the problem of rising market power and the shortcomings of existing policy proposals. Part II develops the theory of equal ownership as a response to rising market power. It shows how moving toward broader socio-economic ownership of corporations has the potential not only to lessen the distributional harms of excess market power, but also to push firms toward behavior that mimics firms' behavior in a world of perfect competition. Part III discusses the practical aspects of equal ownership, briefly exploring ways to broaden ownership and to encourage stronger influence by ordinary owners on corporate decision-making. Part IV considers potential challenges to equal ownership and the responses to such challenges.

I. Market Power and Potential Solutions

There is increasing evidence that corporations have exploited their market power in ways that harm consumers and workers. The main responses to those concerns are based on curbing market power by reducing the size of corporations, regulating corporations' conduct, or changing the basic purpose of corporations to incorporate consumer and worker welfare. This Part summarizes that scholarship as background to our alternative approach based in ownership.

A. The Rise in Markups and Inequality

When there are too few competitors or other obstacles to competition, corporations can use their market power to exploit consumers, workers, and suppliers. The most straightforward harms are higher prices for products, lower wages paid to workers, and lower prices paid to suppliers.[27] When there are only a few firms in an industry, a condition known as oligopoly, firms often have the power to raise prices for consumers and make fewer products.[28] Many U.S. industries, including banks, airlines, social media, pharmaceuticals, and

Shareholder Welfare Not Market Value, 2 J.L. FIN. & ACCT. 247 (2017). Hart and Zingales argue that corporations should maximize the pro-stakeholder preferences of shareholders. However, there is little evidence that investors in public corporations, mostly asset managers, have pro-stakeholder preferences that would entail sacrificing profits by reducing prices or increasing wages. *See infra* text accompanying notes 123–133.

[27] Although price is the focus throughout this Article, harms can manifest in many other ways, such as through lower quality products and worsened worker safety.

[28] *See* HAL R. VARIAN, INTERMEDIATE MICROECONOMICS: A MODERN APPROACH 497–521 (8th ed. 2010).

health care, are oligopolies.[29] Similarly, if there are too few firms in a given location employing workers in a specific industry, a condition known as oligopsony, these employers may lower wages and employ fewer people.[30] These states of affairs contrast with competitive markets, in which firms reduce prices and increase wages in order to attract consumers and retain workers.

Antitrust-related channels are not the only significant channels for anticompetitive markups. On the consumer side, for instance, anticompetitively high prices can come through confusing, manipulating, or deceiving consumers. The tactics used in this category are too vast to list. They include shifting more of the price of a printer from the initial purchase to the replacement ink cartridges;[31] hiding fees and price increases in the fine print of mortgage, credit card, and other contracts; and offering complex pricing packages, such as cell phone plans with various charges for data, minutes, and overage fees.[32] Each of these practices makes it more difficult and time-consuming to compare prices, which is problematic because price comparison is necessary for competitive markets to function well.[33] These and other practices have been shown to significantly raise the prices that consumers pay by exploiting either the costs of collecting information or the mind's limits in processing complex information.[34]

While the extent to which competition is declining is widely debated,[35] there is mounting evidence to that effect. Since the 1990s, about 75 percent of U.S. industries have experienced an increase in concentration levels.[36] There is also evidence that markups—the difference between prices and marginal costs of production—have been steadily increasing. Whereas the typical business sold its goods at 21 percent above costs in 1980, by 2016 that figure had risen to 61 percent.[37] This suggests that firms have increased their ability to extract more from consumers.[38]

Likewise, there is evidence that workers are suffering from substantial concentration in labor markets. A recent study finds that more than 60 percent of geographic-occupational markets in the United States are concentrated and that market concentration is associated with

lower wages.[39] The trends in the wage-productivity gap are particularly alarming. Before the 1980s, workers were paid more if they were more productive. But in recent decades, wages have remained mostly stagnant even as workers have become much more productive.[40]

It is not surprising that in the same period, corporate profits and market values of large corporations have increased dramatically.[41] In other words, shareholders are making larger returns, while consumers and workers are relatively worse off. This suggests that owners are benefiting at the expense of other corporate stakeholders.[42] Accordingly, there is a deep concern that market concentration, weak competition, and consumer manipulation contribute to economic inequality across the economy.[43] Since both consumers and workers are made up of all socio-economic groups, whereas owners are much more concentrated among the wealthy, anticompetitive prices and wages transfer resources from lower to higher income groups.[44]

Finally, it is important to emphasize that weak competition is not only inequitable, but it is also inefficient in the sense that it reduces aggregate welfare, or the total welfare of shareholders and society. As we explain below more formally, when firms have market power, they produce lower quantities and employ fewer people, resulting in lower aggregate welfare to the economy as a whole.

B. *Policy Proposals and Their Limits*

The responses to market power can roughly be put into three categories: (1) changing the structure of corporations, such as by breaking them up and thus reducing corporations' market power over their stakeholders; (2) regulating corporations' behavior towards their stakeholders, such as by ensuring that consumer contracts and wages are fair; and (3) empowering corporate boards to take actions that primarily benefit stakeholders rather than shareholders. Each of these options faces significant practical limits.

The two main structural proposals for reducing corporations' market power are blocking a higher percentage of mergers and more aggressively breaking up companies.[45] Critics of these proposals argue that they will wind up harming consumers and workers. Blocking mergers or breaking up companies might make businesses less efficient by removing economies of scale, which could lead to higher consumer prices.[46] Part of the problem is that it is difficult to

accurately predict the magnitude of efficiency savings compared to the magnitude of the market power increase that will result from any structural intervention.[47] In any case, blocking mergers is insufficient by itself because corporations can obtain monopoly status without making any mergers or acquisitions. Yet even if regulators were to execute a breakup perfectly, they would require resources to design and oversee this process.[48] And it is often pointed out that after the breakup of an oligopoly, it is only a matter of time before the industry returns to the same level of monopoly power, as managers seek to obtain it.[49]

The second approach is to regulate the corporation's behavior in ways that push it closer to competitive conduct. One leading behavioral remedy is to require the firm to allow competitors access.[50] For instance, Apple might be ordered to allow competitors to offer apps to Apple customers, even if those apps offer the same services, such as maps or music, that Apple does.

Another set of interventions lie in consumer law. Like the practices themselves, policy recommendations to address consumer law-related pricing strategies are diverse. Although scholars sometimes propose outright banning a practice, more commonly they have recommended laws that introduce behavioral nudges and information disclosures, such as attempting to push consumers toward better choices or providing them (or their digital assistants) with the data they need to make better decisions.[51]

One of the most far-reaching ways to regulate corporate behavior is to limit prices and wages. In some geographies where cable companies have monopolies, for instance, local governments limit the prices for basic services.[52] And minimum wage laws are sometimes justified as necessary to move wages toward the level they would be in more competitive labor

markets.[53] In other words, rather than increasing competition, price and wage restrictions seek to mitigate the resulting harms.

Although at least some of these proposals have promise,[54] they also face limitations. Among the many limits of such behavioral regulation, a chief one is the difficulty in designing and enforcing an intervention. It is difficult to know what level of wages or prices will not deter companies from hiring workers or from investing in consumer services and innovation.[55] Similarly, managers often find new ways around regulation, even price regulation. For instance, cable companies responded to price regulation by creating complex contract structures with hidden fees and equipment charges that technically met the base price restrictions but still allowed the cable company to charge functionally anticompetitive prices.[56] And access remedies require the government to police various day-to-day decisions inside the firm about which competitors can have what kind of access while the monopoly continually innovates and creates subtle barriers to block the competitors who are supposed to have that access.[57]

In short, one of the main limitations of structural and behavioral interventions is that they require external actors who are less sophisticated and under-resourced, such as courts and government regulators, to make complex market decisions, which they may be ill equipped to make. Moreover, managers then have the incentive to find ways around those interventions.

The last approach is rooted in reforming the management of corporations. The idea here is to change the purpose of corporations themselves by requiring corporate boards to maximize stakeholders' value rather than just shareholder profits.[58] The intuition behind this idea is that corporations that are single-mindedly focused on profits are more likely to exploit their stakeholders. Proponents reason that a stakeholder-oriented firm would act more fairly towards consumers and workers and thus, despite its market power, choose to charge lower prices and pay higher wages.[59]

[59] To be sure, the stakeholder model is not specifically designed to address the problem of market power, and it extends to other social goals, such as protecting the environment. However, as consumers and workers

The challenge with this idea, however, is that stakeholder models ultimately rely on managerial discretion. That is, managers have the discretion to make decisions based on whether they benefit stakeholders, and they are supposed to balance the interests of stakeholders and shareholders. But managers are primarily answerable to shareholders. Shareholders have the power to appoint the board, and the board appoints the CEO and the leading executives of the corporation. These executives are paid mostly with stocks and options to ensure that they have strong incentives to maximize value for shareholders.

This incentive structure reflects the preferences of the shareholders of public corporations, the vast majority of whom are institutional investors,[60] which presumably want their investment portfolios to have the highest possible return.[61] In fact, their fiduciary duty is to act in the interests of their beneficial investors by maximizing the risk-adjusted returns of their portfolios.[62] While it is true that institutional investors have been increasingly more vocal about social issues, the evidence to date suggests that they are primarily focused on profit-maximization.[63]

Within this framework, it is unrealistic to rely on managers to set prices and wages in a way that compromises shareholder value to benefit stakeholders. Moreover, because managerial discretion is protected by the business judgment rule, managers may simply claim that their decisions are giving adequate consideration to the interests of stakeholders. In fact, that's what managers often do in order to boost their companies' reputations as being socially responsible.

Accordingly, none of the well-known legal mechanisms for addressing market power are likely to be sufficient in eliminating anticompetitive profits. This partly explains why the goalpost of perfect competition that maximizes consumer and workers' welfare is elusive in practice. We do not suggest that existing mechanisms for addressing market power are entirely useless and should be cast aside. Rather, we argue for an additional policy channel that would complement existing approaches and could potentially be more consequential.

The main advantage of equal ownership is that unlike existing approaches, it does not seek to fundamentally alter the basic structure, conduct, and norms of corporations. Equal ownership does not require aggressive antitrust interventions to increase the relative bargaining power of stakeholders, costly regulation of corporations' behavior toward stakeholders, countering the marketing group's inclination to set prices as high as possible, or jettisoning the shareholder primacy norm in favor of a stakeholder model. The idea is simply to allocate to stakeholders, particularly consumers and workers who belong to lower income groups, a greater share of public corporations. Because equal ownership is a less drastic

remedy, it offers a more actionable path for tackling the growing market power of corporations.

II. THE THEORY OF EQUAL OWNERSHIP

In this Part we demonstrate how changes in ownership may respond to concerns about anticompetitive corporate behavior. After laying foundations from the theoretical literature on corporate ownership, we discuss the two main ways that equal ownership may influence market power. The first is that some of the surpluses from market power would flow to the consumers and workers as owners of the corporations. The second is that to the extent that corporate managers may internalize owners' preferences, they will incorporate the interests of consumers and workers in making business decisions.

A. Ownership by Stakeholders as a Response to Market Power

The focus of our analysis is on the extent to which ownership by stakeholders may serve as a response to market power. The idea of broadening the ownership base of corporations and extending it to a wider section of the population has been proposed in various shapes and forms.[64] However, these proposals have overlooked the role of ownership in mitigating the costs of market concentration and exploitative contracting. The relationship between ownership and market power has been articulated in Henry Hansmann's seminal 1996 book, *The Ownership of Enterprise*. In this book, Hansmann lays out a theory of ownership that explains how consumers or workers might become owners as a means of avoiding exploitation by monopoly or monopsony firms.[65] Hansmann's basic idea was that the firm will internalize the interests of its owners.[66] Consequently, if those owners are also the firm's consumers or workers, the firm should have weaker incentives to exploit them.[67]

Hansmann reasoned that when a firm has market power with respect to one or more affected groups, those groups have incentives to own the firm by forming a cooperative in order to avoid price exploitation.[68] By owning a firm that has market power, customers can avoid the costs of paying a monopoly price for the goods or services that they purchase from the firm.[69] At a minimum, the monetary fruits of any surpluses in transacting with the stakeholders will simply flow back to the those stakeholders if they are the sole owners of the firm.

A simple example of a consumer-owned cooperative is a retailer-owned wholesale cooperative in the grocery business, where a few wholesalers enjoy considerable market power, and large chains have their own wholesale distribution systems.[70] The retailers avoid exploitation by owning wholesalers that serve them. Other examples include mutual banks

owned by the bank's borrowers who seek to avoid exorbitant interest rates[71] or farmer-owned cooperatives who buy produce from individual farmers at fair prices and sell it to retailers.[72]

A significant policy limit to these insights is that these companies tend to be small or at least face substantial impediments to scaling. While some have highlighted the benefits of cooperatives and suggested policies for further expanding their uses,[73] the main challenge for cooperatives is reaching scale. Because ownership is restricted to a particular set of stakeholders, such as consumers or workers, it is difficult for firms to attract equity capital from investors.[74] Thus, despite providing intellectual foundations for a path forward, these examples of stakeholder ownership are unlikely to provide a broader solution to corporations' contributions to economic inequality.

Our idea of equal ownership extends on Hansmann's insights in that he focuses only on well-identified groups of owners as a means of influencing managers' corporate decisions. Equal ownership is much broader in that it contemplates consumers and workers owning a diversified portfolio of public firms' stocks.[75] The firms that consumers buy from or workers work at will make up only a fraction of their portfolio—and only if they buy from and work in public firms. In contrast, in a mutual or worker coop, the ownership is entirely by the consumers or the workers of the firm itself.[76] Thus, Hansmann focused on ownership structures that enabled the sharing of surpluses that firms extracted directly from their stakeholder-owners. In contrast, the thrust of our proposal is primarily to enable consumers and workers to share in public firms' profits as a form of insurance against corporations extracting supra-competitive profits earned generally across markets.

There are essentially two channels though which equal ownership can address market power and surplus. The first is the distributional channel, which means giving people a share of the rents that corporations extract from the people. The second is the governance channel, which is that to the extent that managers are attentive to their owners' preferences, and that owners are regular people who prefer corporations to act fairly towards consumers and workers, corporations will be less likely to exploit their market power by charging excessive prices or paying low wages. We discuss each of these channels in turn.

B. *The Distributional Effects of Equal Ownership*

To better understand the distributional appeal of equal ownership, it is necessary to consider the market goal post used by economists for decades: perfect competition. To streamline the exposition, we focus the analysis on consumer markets, but equal ownership has similar implications for other markets, such as labor markets. In the context of consumer

markets, perfect competition is a hypothetical market defined by characteristics such as a large number of sellers and consumers possessing adequate information to make informed decisions and ideally ease of market entry for new competitors.[77] The socially desirable outcome from an antitrust perspective is to move from a state of oligopoly, in which each market is dominated by a few firms, toward perfect competition.

Under perfect competition, firms lack the market power to charge higher prices for the same quality of product, and they set the price of the goods to their marginal costs, such that firms' profits are theoretically zero.[78] To state the obvious, when the price is lower, the distributional benefits to consumers are larger. More precisely, perfect competition enables consumers to capture the maximum possible value of what economists call "consumer surplus." The consumer surplus is simply the difference between the maximum price that consumers are willing to pay for a product and actual price paid for the product. In an oligopolistic market, the consumers extract a smaller consumer surplus than in a world of perfect competition. The greater the market power of the firms is (i.e., when there are fewer firms), the smaller the consumer surplus. Thus, market power redistributes from consumers to the firm: consumers pay more for products, and the firm earns greater profits at their expense.

Equal ownership essentially means that the consumers are also owners, and thus by definition, they get a share of the profits of the firm. It is widely accepted that perfect competition is not attainable and that corporations extract some surplus. Nonetheless, more equal ownership allows consumers to recoup a portion of that surplus by sharing as owners in the profits of the firm. Stated otherwise, equal ownership allows consumers and workers a share of the profits resulting from any anticompetitive profits and wages. Equal ownership thus mitigates the residual rents corporations extract from consumers and workers that are not addressed through regulation. Thus, equal ownership is different from leading proposals to address market-related inequality in that our proposal does not require fixing market failures to produce a distributional benefit.[79]

In Appendix A, we provide a simple model of an oligopoly using the influential Cournot model.[80] Cournot is a simplified model, like other leading economic models used in antitrust policy, and thus has limits because the real world is more complex and nuanced.[81] Nonetheless, the model is widely used to evaluate the effects of limited competition and antitrust policy and adjudication.[82] This simple model provides a numerical example of the impact of market power on consumer welfare.[83] It then shows that share ownership allows consumers to have a greater

[83] The basic assumption in the model is that there are a few firms that all produce one homogeneous product.

share of total welfare, which includes the joint welfare of both the firm (i.e., its profits) and the consumers.

The above analysis is very similar in the context of workers and suppliers of input. For example, in concentrated labor markets, firms may set lower wages that are below their marginal productivity. The worker surplus is lower because fewer people are willing to work for such low salaries, and thus market power diverts wealth from workers to corporations.[84] And the same applies to suppliers who sell their products to a few large firms with market power and pay them below competitive prices for their products. Likewise, equal ownership will allow workers and suppliers to share in the profits, which are partly the product of the profits made at their expense through anticompetitive conduct.

Thus, equal ownership fills some of the distributional gap inevitably left between perfect competition and real markets. As shown in Figure 1, households with incomes below $180,000 experienced a sharp decline in share of ownership of public corporations in the past twenty years. Reversing this trend may therefore mitigate the harmful consequences of market power.

This simple analysis ignores, however, what is arguably the key problem of market power, which is that it creates a deadweight loss. Deadweight loss is the difference in total wealth to both firms and their stakeholders between the perfectly competitive economy and a concentrated market. In consumer markets, it reflects all lost surplus to consumers and firms that would have transacted for the lower competitive prices. All that equal ownership does, based on our assumptions thus far, is redistribute profits to consumers and workers. It does not salvage the deadweight loss as compared to a perfectly competitive world. The reason for this is that the managers only seek to maximize profits but do not consider the interests of their owners who are consumers. In the next section, we explain how equal ownership might improve total welfare by reducing the deadweight loss.

C. The Governance Effects of Equal Ownership

In the previous section, we assumed that managers maximize firms' profits, irrespective of who their owners are. In this part, we show how equal ownership could produce even better outcomes if managers internalized the interest of owners who are stakeholders, such as consumers and workers. The intuition behind equal ownership having market benefits beyond distribution begins with the observation that when the owners are also consumers, those owners would prefer that the firm treat them better as consumers. If managers internalized that preference, they would set prices lower than their market power allows, which is closer to competitive prices.

To understand the importance of that insight, we consider again an oligopolistic industry using the Cournot model we introduced in the previous section. In this setup, the firms with market power choose the quantity of the products, which determines the price of the products. The model shows that when firms have market power, they produce fewer products and thus increase the prices. Within this framework, the typical approach is to assume that the firm and

---

All the firms have substantial market power in the sense that their decisions to produce the product affect the good's price. The firms compete by setting the quantities rather than price, and the product's price decreases when quantity is larger. All firms set the quantity they produce to maximize profits. They take the output of the other firms as given. The market price is set at a level such that the demand equals the total quantity produced by all firms. *See id.*

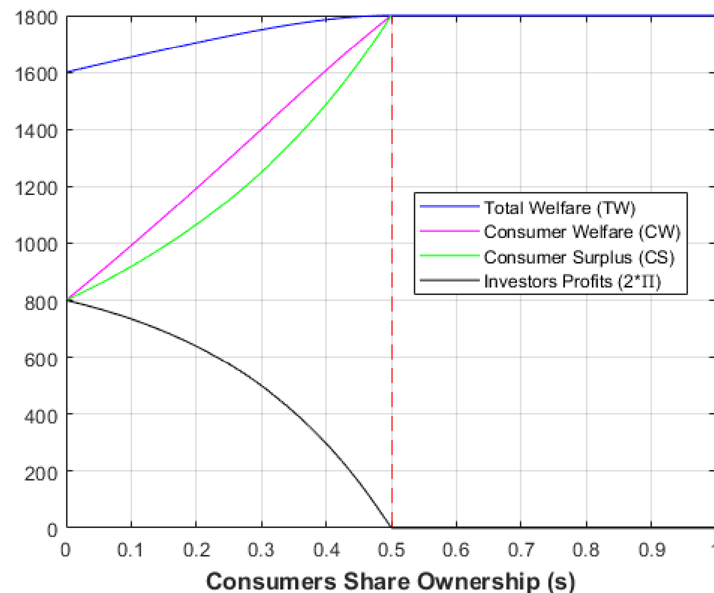
[84] POSNER, *supra* note 4, at 16.

its owners are focused on maximizing profits.[85]

We vary the basic Cournot model so that all consumers have shares of ownership of all the firms in the economy.[86] In our model, we assume that when consumers have a share in the corporation, the corporation considers the interests of investors who are both consumers and non-consumers of the firms' products.[87] For non-consumer investors, such as investment funds, the model assumes that they care exclusively about profits.[88] The specific details are described in Appendix B, and here we describe the main results and intuition for them.

When we introduce this ownership twist into the basic Cournot model, it gives the result that managers decide to produce higher quantities than in the standard Cournot model. That decision to produce higher quantities drives the price of the product lower. This further results in greater consumer surplus and lower firm profits. These findings show that equal ownership can, in theory, bring about the kind of socially desirable outcomes as those sought by many calling for stronger antitrust enforcement.[89]

Figure 2: The Effect of Consumer Ownership on Welfare



[85] The exception to this is the literature on common ownership, which assumes that firms are interested in maximizing the aggregate profits of the portfolios of their owners who own shares in other competing firms. *See* sources cited *supra* note 17.

[86] Again, although we focus on consumers, the theoretical analysis applies with equal force to workers and producers.

[87] Thus, if s is this share of ownership held by consumers, the firm will give a weight equal to $1-s$ to the interests of profit-seeking investors, and a weight of s to consumers who want to maximize both profits and the consumer surplus. We further assume that the firm is still subject to the constraint that it must make nonnegative profits, and therefore the firm will not make decisions that cause it to essentially become bankrupt.

[88] This is of course an illustrative account, and we discuss the real work complexities of this account in Section III.A below.

[89] *See infra* Appendix.

Importantly, using our Cournot-ownership model we obtain the result that total welfare, which includes the aggregate welfare of consumers and investors, increases when firms internalize the interests of the owners who are consumers. In fact, at the optimal point of share ownership, total welfare is exactly the same as in the case of perfect competition. The reason is that at lower prices, there is no deadweight loss resulting from consumer who would not buy the products at higher prices. The results of this analysis are shown graphically in Figure 2 for a Cournot model with two firms in the market (see Appendix B).[90] As shown in the figure, the optimal level of consumer ownership in the example we examine is where 50 percent of the firm is owned by consumers.[91] At this point, firms choose to produce the product at the competitive price, which is equal to the marginal cost of producing a product.[92] When ownership is increased above 50 percent, the welfare results remain at that same level. That leveling off reflects an assumption that the firm will not lower the price below the marginal costs of producing the product. In any case, the key take is that total welfare and consumer welfare increase with consumer ownership up to the point at which the market outcomes are equivalent to perfect competition.[93]

This basic analysis can be applied to other stakeholders, such as workers and suppliers, although it requires some elaboration. If we consider employment, in a market with few firms, the number of jobs would be smaller, and wages would be lower compared to those in a competitive market. Equal ownership could mitigate this problem if managers internalize workers' preferences for higher wages.

The analysis here is slightly different than that in the case of consumers because the managers here would maximize shareholder-workers' preferences rather than pure profits.[94] However, recall that with equal ownership, workers would have a share in a broad section of public corporations, including the company they work for, but mostly many other firms. In theory, these workers will prefer that only the firm they work in will increase wages and that all other firms will reduce wages. But such preferences would be counterproductive. The workers of each corporation on their own would have too little stake for managers to change

[90] When s=0, we see the baseline total welfare, consumer surplus, consumer welfare, and firms' profits under the Cournot model when the consumers have no ownership interests. As s increases, we see that firms profits decreases and consumers surplus increase. The reason is that the firm produces more quantity at a lower price. The consumer welfare increases as well and it is higher than the consumer surplus because it includes both the consumer surplus and the consumers' share of the firms' profits.

[91] Of course, we do not suggest that 50% is exactly the optimal share ownership, and this figure is driven by the assumptions we make in Appendix B. The point is that there is some share ownership level above which the price of the product will be equivalent to the competitive price.

[92] At this point, firms' profits equal zero, but that still means owners receive a competitive return on their investment—the firm simply does not receive anything above that.

[93] We acknowledge that this is a stylized model, and the results are driven by assumptions. For example, we assume that the consumers who are owners care about consumer surplus just as much as they care about the firms' profits. But, naturally, the extent to which they care about that surplus depends on how much they consume. It is possible that the weight that consumers themselves would assign to consumer surplus is lower than assumed in the model, and therefore the firm itself would give a lower weight to sharing that surplus with consumers. Regardless, the firm would still move directionally toward charging more competitive prices, resulting in greater benefits for consumers. Thus, while the model, like the Cournot model itself, cannot offer absolute precision, the upshot of the analysis remains intact. For a discussion of the Cournot model's value, see, for example, AREEDA ET AL., *supra* note 80.

[94] As discussed above, this is consistent with Hart and Zingales who argue that corporations should maximize the pro-stakeholder preferences of shareholders. *See supra* note 26.

the firm's wage policies. They would thus need the support of other worker-shareholders for managers to internalize a general preference for higher wages. Moreover, workers further have an interest in supporting higher salaries at other firms because those higher salaries will increase the pressure on the firm they work for to increase salaries as well.[95] Relatedly, since workers often switch employers at some point, higher wages at other firms create more attractive exit opportunities.

Accordingly, we think that workers, that is people who make their living primarily from earned income, would prefer corporations they own to pay higher wages. And if managers internalize these preferences, equal ownership will result in higher wages. Moreover, if workers' ownership share is large enough, it could mimic the competitive wage and maximize total welfare.

* * *

It is now possible to see how equal ownership could address the central limitations of the stakeholder model of the corporation. Existing stakeholder proposals seek to empower managers to pay more attention to non-owner stakeholders without direct accountability to those stakeholders. By making stakeholders owners, corporate managers become more directly accountable to these stakeholders' financial incentives. Thus, unlike many stakeholder approaches that seek to pressure managers to go against owners' interests, equal ownership encourages managers to pay more attention to owners' interests. Rather than pushing against the relationship at the heart of the corporation, that between owners and managers, equal ownership operates within it.

Additionally, in comparison to other institutional responses to market power, such as breakups or regulation, equal ownership does not depend on government actors with limited resources, sophistication, and information. Because firms know considerably more about their own operations and their customers, and generally have greater sophistication, managers are better positioned to efficiently design and implement the quality, quantity, and pricing mechanisms for achieving perfect competition.

A key practical challenge for our theoretical claims is that it is not clear how big of a stake would stakeholders need to hold in order for managers to care about their interests. After all, currently corporations are overwhelmingly owned by a small slice of the population. Even if ownership were broader, it not clear that the managers would maximize the interests of shareholders beyond profit, because the owners would still need to find a way to express their preferences to managers. However, the question of whether firms internalize the interests of their stakeholder-owners is not binary in the sense that the firm either internalizes those interests or does not. The more the firm internalizes the interests of stakeholder-owners, the more equal ownership would push oligopolies towards more competitive behavior. In the next Part, we delve into the institutional design of equal ownership, which seeks to address some of these practical challenges and increase the likelihood that the firms will act in a way that is consistent with consumers and workers' preferences.

[95] To be sure, we do not claim that all firms automatically adjust their wages to those of their competitors and in many cases, they prefer to compete by keeping wages low to increase profits. But at the very least, higher wages at other firms will at least increase the pressure to increase wages by attracting more talented workers to those firms.

III. Institutional Mechanisms to Implement Equal Ownership

The previous Part developed the theory for equal ownership's economic benefits. But implementing equal ownership would also involve two main practical steps that would benefit from some development. The first is expanding ownership so that more households beyond the wealthy own stocks. The second is ensuring that those owners influence corporate managers' decisions in ways that are consistent with sharing surplus. These two aspects are related to one another. The greater the share ownership of consumers and workers, and the more that they can influence managers' decisions, the more likely it is that equal ownership will result in outcomes that resemble those in more competitive markets.

A. Encouraging Broader Ownership

This section contributes to the literature a brief overview of possible paths to broadening ownership of corporations to all segments of society, including some novel ideas for doing so.[96] As shown above, the share ownership of the bottom 90 percent in wealth has declined dramatically in the past twenty years.[97] Broadening ownership thus means instituting policies that would expand ownership beyond the very wealthy segment of the population. In this section we are indifferent as to the form of ownership (i.e., retail or institutional) and focus on the various policy options for encouraging broader ownership. Rather than propose a particular policy, we see this array of options as a menu from which legislators can choose. The options are not mutually exclusive and thus may be pursued simultaneously.

Before discussing specific policies, we emphasize that not everyone needs to own substantial portions of the stock market to receive considerable benefits from expanded ownership. For instance, households between the 50th percentile of income and the 90th percentile of income—roughly the upper middle class and well-off but not rich—own about 11 percent of corporate stocks but account for roughly 66 percent of consumer spending.[98] Those households would overall prefer that corporations charge lower prices because they compose a much greater percentage of consumer spending than they do of ownership. It is not unreasonable to contemplate a world in which they own 22 percent of public corporations (as was the case twenty years ago[99]) or possibly a larger share (say 30 percent). Our analysis suggests that such shifts in ownership could influence the conduct of corporations to set more competitive prices and wages.[100]

We first consider the question of who will actually pay for the stocks on behalf of individuals. The three main potential funders are wealthy donors, the government, and individuals themselves. Relying on donations by the wealthy may be attractive because this path does not depend on either tax dollars or spending by individuals with tight budgets.[101]

[96] *See* Stout et al., *supra* note 10, at 49.

[100] *See supra* Part II.
[101] Most notably, Stout, Gramito, and Belifanti propose expanding ownership solely by this method. *See* Stout et al., *supra* note 10, at 119–24.

The government could encourage such donations by providing donors with tax deductions.[102] To ensure donors do not attempt to boost the stock price of firms they have a stake in, either beneficiaries themselves or an intermediary on the beneficiaries' behalf would make the actual choice of which stocks to buy.[103] However, philanthropy may never materialize in any substantial amount, and therefore it is worth considering other paths.

The most straightforward way for the government to expand ownership would be for it to purchase shares on behalf of low-income individuals. Although the political will for such expenditures may not materialize during normal times, the federal governments is more likely to consider stock ownership to address wealth inequality during economic crises. There are macroeconomic contexts within which the government must infuse money into capital markets to avoid economic collapse. During the 2008 financial crisis, for example, the U.S. Treasury injected hundreds of billions of dollars into corporations.[104] Then again, in 2020, as stock markets plummeted upon news of the coronavirus outbreak, the Federal Reserve pumped over a trillion dollars into capital markets.[105] The next time the federal government decides to direct massive amounts into corporations, it could in exchange require increased stock ownership for the bottom 90 percent of households.

Other avenues for equal ownership exist without any government purchases or private donations. For upper middle-income individuals who have more ability to invest, tax incentives can encourage equal ownership. One way to design such incentives would be to lower the taxes on small-value trading. Currently, investors pay capital gains taxes when they sell a stock for profit after a short period. Those taxes discourage stock ownership by making it less financially lucrative to invest.[106] If taxes on small-value trades were lowered or eliminated, purchasing small amounts of stocks would become more affordable to individuals with limited resources.[107]

Wealthy interests have heavily lobbied for capital gains tax reductions, making tax incentives a potentially more politically feasible policy option. On the other hand, tax incentives would still require middle-income households to make purchases from what is often a tight household budget. It is thus worth considering whether there is a way to leverage existing sources of household wealth.

One of the largest sources of existing household wealth that might be repurposed is Social Security savings. Social Security wealth – defined as the total value of Social Security benefits

[107] This form of phaseout may be justified on the basis that ownership by lower income individuals generates at the margin larger positive benefits than ownership by higher income people. owed to individuals – is estimated at $30 trillion to $45 trillion in 2019.[108] Another area in which the bottom 90 percent of households has substantial wealth is in bank deposits, valued at over $1.5 trillion dollars.[109] Thus, it is worth thinking about how these sources of wealth might be held in a way that would provide more of an ownership stake in corporations until that wealth is withdrawn.

There are various ways that such repurposing programs could be designed. A portion of Social Security could be invested in the stock market on behalf of individuals who made social security payments throughout their life. Naturally, leveraging Social Security for stock ownership would require a change in the way that Social Security taxes are being utilized. Currently, such taxes are mostly used for federal budget expenditures rather than held directly on behalf of individual payers.[110] Alternatively, a portion of Social Security taxes can be directly invested on behalf of taxpayers.[111] Although investing such payments in stocks would involve some risk in the case of a market downturn, the current system of the federal government essentially borrowing the money from the taxpayers and promising to repay it in the future is not free of risk.[112]

In terms of bank account savings, for the sake of illustration, consider that financial regulation currently limits what banks can do with deposits. In particular, banks cannot invest more than a fraction of customer deposits, such as about 10 percent depending on the bank, in stocks.[113] What deposits banks do put toward stocks yield profits for the bank, not for the deposit holders.[114] One way to increase the bottom 90 percent of households' ownership share would thus be to design a mechanism for some portion of those savings to be automatically converted to stock ownership as a default. Depositors could opt out if they did not want to participate. However, the savings could be essentially insured from stock market losses, which is not a substantial expansion of insurance that is already provided to customers through FDIC insurance and to the biggest banks in the form of implied bank bailouts.[115] Many further details

would of course need to be ironed out, such as constraints on banks' abilities to invest the funds and how the profits from such investments would be allocated.

In summary, there are various avenues for expanding the ownership base of corporations. Again, the point here is not to argue that any particular mechanism is necessarily better than others, but rather to show that one or more feasible options could be designed.

B. Encouraging Stronger Influence by Owners

Equal ownership's potential to mitigate the harmful effects of concentrated markets depends in large part on the extent to which managers internalize owners' interests as consumers, workers, and suppliers. An obstacle to that internalization is the core problem that has animated corporate governance from the field's beginning: agency costs. In the traditional analysis, the problem is that managers may engage in wasteful projects or shirk on their duties instead of maximizing profits on behalf of shareholders.[116] That problem imposes costs on shareholders in the form of lower profits. In contrast, our concern is with the likelihood that managers make decisions that benefit their stakeholder-owners beyond simply profit, to include other interests like paying lower prices and earning higher wages.

To elaborate, a challenge facing equal ownership is that if the shareholding of average people were to increase, managers would simply neglect their interests.[117] As is well known, the costs of collective action for dispersed shareholders are high, resulting in managerial entrenchment and shirking.[118] Moreover, less wealthy disaggregated individuals may have insufficient expertise, information, and sophistication in monitoring managers. Shareholders' failure to monitor managers or managers' inattentiveness to shareholders could make the governance effects of equal ownership inconsequential.

In modern markets, most public stocks are held by institutional investors. In recent decades institutional asset managers, like BlackRock and Vanguard, have gradually increased their ownership stakes, and they nowadays own about 72 percent of public stocks.[119] Thus, a natural way to broaden the ownership of public corporations is not by increasing retail ownership, but by increasing stakeholders' investment through mutual funds and pension funds.

The question then becomes to what extent such institutions would actively cause managers to make decisions about prices and employment that are conducive to the interests of some of their underlying investors. Due to their size and resources, institutional investors were

supposed to solve shareholders' inability to act collectively and monitor managers.[120] However, asset management has created another layer of potential agency costs, which is the risk that these asset managers fail to serve the interests of their own investors.[121] There is a lively debate about the extent and nature of these agency costs, and most of it focuses on whether institutional investors are too passive or too active and whether their actions actually improve firm performance.[122] This debate centers on maximizing shareholder economic value as the main objective of institutional engagement.

Institutional investors, however, are increasingly aware that they are expected to ensure that their portfolio companies are run in a socially and environmentally responsible manner. Leo Strine, former Chief Justice of the Delaware Supreme Court, expressed the concern that asset managers' pressure on firms to pursue profits is too strong and may be detrimental for ordinary people.[123] Larry Fink, the CEO of BlackRock, has repeatedly stated that the purpose of corporations is to promote social welfare and not just maximize profits.[124] Moreover, because institutional shareholders make their income from fees based on the amount of assets they manage, they have started marketing their social responsibility actions to potential clients, who are arguably socially minded.[125] The amount of assets invested in environmental, social, and governance ("ESG") funds has grown dramatically in recent years and is expected to continue growing in the coming years.[126]

These developments suggest that there is a possibility that if more stakeholders invest in the market through institutional investors, these investors would face competitive pressures to promote causes that enhance consumer and worker welfare.[127] Institutional investors may make shareholder proposals that require firms to increase wages or reduce prices. Even without equal ownership, the number of shareholder proposals relating to environmental and social matters has been increasing, such that as of 2022 they form more than 80 percent of shareholder proposals.[128] These include proposals urging corporations to reduce prices for consumers[129] and consider increasing wages for workers.[130]

Likewise, institutions may vote for directors who specifically seek to improve consumer and worker welfare, therefore withholding votes from those that do not.[131] Institutions may even use their advisory votes on executive compensation schemes to push for tying compensation to better treatment of consumers and workers.[132] Managers would still have incentives to maximize profits, but they would be encouraged to pursue greater profits without increasing prices or paying low wages.[133]

To be sure, there is already a serious concern as to whether institutions' current focus on ESG is merely an exercise in greenwashing.[134] One key reason for questioning the impact of ESG investing is that it is often difficult to measure whether ESG standards, which are very general and broad, truly promote practices that are beneficial for society.[135] Moreover, many ESG practices are designed to increase risk-adjusted returns and are thus entirely consistent

with profit maximization.[136] But the present status of ESG may be partly driven by the fact that underlying investors in institutions are primarily wealthier individuals whose wealth is unlikely to be affected by product prices or wages. In the world we are contemplating, a greater percentage of investors would be interested not just in profits, but also in maximizing consumer and worker surpluses.

In a world of more equal ownership, stronger accountability to owners is thus desirable from a social perspective.[137] This is counterintuitive because the standard critique of expanding corporate governance to include a broader set of stakeholders' interests is that doing so might lower total economic welfare.[138] The basic reasoning underlying that concern is that the pursuit of profits by all corporations enhances competition, which in turn maximizes total welfare; thus, pushing managers to consider issues beyond profit could move markets away from the ideals of perfect competition. But, in a world where firms have market power, our theory shows that if managers internalize owners' preferences as stakeholders, total welfare is actually higher. Giving stakeholders an ownership stake therefore bolsters the normative justification for stronger corporate governance and mitigates the concern that stronger governance would harm ordinary people.

Although we do not propose any particular mechanism for increasing internalization of stakeholder interests, many options exist. The most straightforward way of making firms internalize the surplus interests of owners would be to require expanded duties of institutional investors. In consumer finance, lenders are required to "know your customer," referring to the importance of checking income carefully and extending only loans that the customer can repay.[139] Institutional investors might similarly be required to "know your shareholder," or have a sense of where their shareholders' interests are, and to make some good faith efforts to vote accordingly.[140]

Information technologies would help lessen the costs of knowing shareholder preferences. Indeed, apps might help translate institutional ownership into a more direct form of representative governance by sending notifications for the type of elections or issues that are coming up in director voting. Interestingly, BlackRock pledged to give its clients greater say in

[140] Fisch and Schwartz argue for requiring managers of mutual funds and pension funds to seek input from their beneficiaries on their views on social and environmental issues and reflect those views in both their engagement efforts and their votes. *See* Jill E. Fisch & Jeff Schwartz, *Corporate Democracy and the Intermediary Voting Dilemma*, TEX. L. REV. (forthcoming).

its choices in shareholder votes[141] and even started providing a pass-through voting option to its institutional clients.[142] This suggests that institutions may be developing the mechanisms needed to give underlying investors the ability to express their preferences.

More specifically, it is worth considering whether institutional investors like BlackRock or banks that might invest customers' deposits in the stock market should be required to allow third parties to develop services, such as voting apps, that would communicate with and engage shareholders. The mandate might even require the institutional investor to allow those apps to vote on the behalf of end shareholders, in proportion to the apps' clients' holdings. Thus, the institution would manage the investment but not the voting, at least for those who opt into the third-party apps. Importantly, these apps could be designed to allow time-pressed and unsophisticated equal ownership stockholders to delegate all the voting for their shares to a third party that would be better situated to determine, for example, what corporate policies would be more likely to share consumer and worker surplus with those owners.

Although the discussion has so far focused on institutional investing, an alternative for strengthening internalization could be to encourage retail investors to play a more active role in governance.[143] The challenge is to get retail investors to influence corporate decision-making. The general perception of retail investors is that they are naïve and uninformed and would generally have limited ability to coordinate their positions or influence the composition of corporate boards. However, recent research suggests that at least a subset of retail investors are actually highly involved in corporate voting. Specifically, there is evidence that they punish the management of poorly performing firms, as proxied by low valuation, low profitability, and stock price performance.[144] This evidence suggests that retail investors may be able to express their preferences in corporate decision-making. Thus, if a greater percentage of shareholders would prefer managers that make decisions that are favorable to stakeholders, these shareholders might actually make an impact on corporate decision-making.

The GameStop episode also illustrates potential mechanisms for retail corporate influence. In early 2021, retail investors bought shares of the company, causing share prices to rise by over 1000 percent and squeezing sophisticated investors that shorted the stock.[145] These retail investors coordinated their purchases through social media outlets, seemingly overcoming collective action problems.[146] Although GameStop investors were motivated by personal affinity with the brand rather than the motivation we outline for equal ownership, it shows that retail investors may be able to coordinate with one another when they believe it is in their

interest to do so. Thus, retail investing may potentially reduce the power of institutions that focus primarily on profit and enable greater engagement by ordinary individuals in social issues.[147]

To tie the GameStop episode to more systemic corporate governance, it may be possible to leverage corporate governance digital intermediaries in a way similar to that discussed above for institutional investors. Retail shareholders might communicate their general preferences to some digital intermediary that proxy votes on behalf of a large number of shareholders. For example, their preferences could include a preference for maximizing their overall financial situation, including consumer prices and employee wages. The digital intermediary would then, for each director election, shareholder proposal, or other issue, vote according to the retail investor's communicated preferences.[148]

Overall, this discussion shows that there are a range of possible retail and institutional governance mechanisms for encouraging owners to better internalize the economic welfare interests of different types of shareholders. Implementing these mechanisms may bolster equal ownership by making managers more attentive to the interests of their owners whose wealth is sensitive to changes in consumer prices and market wages.

IV. POTENTIAL CHALLENGES TO EQUAL OWNERSHIP

Equal ownership is not without limits and risks. This Part surveys some potential issues that might arise. Since equal ownership is novel, can be built in many different ways, and would inevitably be implemented gradually, it would be necessary to continually study the impact of broader ownership closely and adjust accordingly. Thus, the discussion below ultimately begins to map some topics for future research.

A. Limits on the Influence of Stakeholder-Owners

Equal ownership will be constrained by two main factors: the distribution of ownership of public shares and the salience of the possible harm. First, the more evenly and widely distributed stock ownership is, the more likely equal ownership will be to push managers to pursue policies that reflect the interests of lower-income groups. There is a concern that even with significant public expenditures, shareholding would likely remain skewed toward high-income households that are less affected by product prices or wages.

Thus, to be highly consequential, the ownership stake of middle- and low-income individuals must be sufficiently high, so that either the distributional or governance effects of equal ownership will be meaningful. Thus, policies to encourage broader ownership, such as tax incentives, must be substantial enough to ensure meaningful shifts in the distribution of ownership.

The second factor that could limit owners' influence is the salience to owner-stakeholders of the possible harms of consumer manipulation or market power.[149] Some consumer

[148] The specific details would need to be worked out for such a proxy to work, such as the duties to the owners or what information would need to be disclosed to the retail owner.

[149] An example of visible harm may be Amazon denying worker breaks. *See* Zahra Tayeb, *Amazon Hit with Lawsuit Over Claims that It Failed to Provide Employees with Required 30-Minute Lunch Breaks,* BUS. INSIDER (Mar. 28,

manipulation or monopoly pricing may remain imperceptible to most people. Indeed, even markets controlled by a few firms may appear to be competitive to the naked eye. For instance, the existence of multiple gas stations in the neighborhood does not mean that oil oligopolies are not charging higher prices to those gas stations. Moreover, the magnitude of price manipulation, monopoly pricing, or monopsony wages may be less observable or seem less important than shifts in the value of individuals' stock portfolios.

However, this challenge is not unique to our proposal. Regulators struggle with this task on a regular basis. We anticipate that shareholders will be aided by the work of consumer protection and competition authorities. Investigations by the Federal Trade Commission or the U.S. Department of Labor will inform shareholders about potentially exploitative practices.[150] In fact, whereas such authorities face political challenges in bringing action to address anticompetitive behavior, shareholders may be less constrained in their ability to pressure managers to reduce prices or increase wages because they will not have to follow a formal legislative or judicial process. For example, antitrust investigations could lead shareholders to bring shareholder proposals for fairer prices or vote for directors who are more attentive to stakeholders' interests. Thus, shareholder pressure can complement and reinforce the work of regulators.

B. *Costs of Collective Decision Making*

Another challenge for equal ownership is that it might raise the costs of decision-making in corporations. A broad ownership base might create conflicts between providers of large amounts of capital and a sizable number of dispersed lower-income people with small investments who are vulnerable to higher consumer prices and lower wages.[151] For example, owners in the bottom 90 percent of households would often prefer low prices and higher wages, while wealthier providers of capital would likely prefer managers to set higher prices and lower wages.[152] Equal ownership might thus turn corporations into a forum where different socio-economic groups battle over different economic outcomes.

The costs of this conflicted decision-making might harm the efficiency of corporations. One of the most attractive features of for-profit firms is that their investors have homogenous

[150] In the context of securities litigation, shareholders regularly piggyback on regulatory actions when they bring a lawsuit against corporations. *See* Emily Strauss, *Is Everything Securities Fraud?*, 12 U.C. IRVINE L. REV. 1331, 1335 (2021).

[151] In general, managers have a duty to act in the best interests of the corporation, which is often viewed as a duty to maximize firm profits. For the classic statement of this duty, see Dodge v. Ford Motor Co., 170 N.W. 668, 671, 684 (Mich. 1919), which notes that "[a] business corporation is organized and carried on primarily for the profit of the stockholders." However, it is well known that managers have discretion to consider a broad range of non-pecuniary factors in making decisions, and their decisions are protected by the business judgment rule. *See* Einer Elhauge, *Sacrificing Corporate Profits in The Public Interest*, 80 N.Y.U. L. REV. 733 (2005). Thus, it is unlikely that courts will intervene in managers' decisions about prices or wages, especially if these are designed to further the interests of the owners themselves. In fact, two leading economists, Hart and Zingales, have recently argued that managers should maximize shareholder welfare rather than shareholder profits. Hart & Zingales, *supra* note 26, at 247.

[152] There may also be conflicts between consumers and workers, for example if managers consider whether to increase prices or cut costs by reducing wages, although it is hard to speculate about the nature of such conflicts at present.

interests in the sense that they are all focused on firm value maximization.[153] If these conflicts are strong enough, they might even reach the boardroom with different board members siding with different factions of shareholders. Likewise, the costs of decisions could also rise if institutions expend more resources soliciting and synthesizing input from shareholders.[154]

This concern should not be overstated in large part because institutional investors themselves already face pressures to be more sensitive to societal interests and because the stakeholders as owners would presumably also be concerned about ensuring that corporations operate in a financially sound manner. Moreover, when making decisions about prices and wages, managers can make compromises by setting them at a level that aggregates the weighted sum of the owners' preferences.[155] This means of course that the final outcomes might not reflect the prices and wages in a perfectly competitive world, but as long as they are substantially closer, equal ownership will have a material impact on social welfare.

C. Excess Demand for Public Stock

Equal ownership would entail an inflow of money into capital markets. By injecting stock markets with a large infusion of investment dollars, equal ownership could distort capital markets.[156] The surge in demand for stocks would drive up prices and increase the risk of economic overheating and a stock market bubble.[157] Although the transition to equal ownership may bring some market turbulence, there are upsides to these dynamics as well.[158] Greater investment capital could spur economic growth,[159] and overall increases in stock prices could help make equal ownership more politically and economically attractive to those with great wealth—especially compared to the alternative possibilities for addressing inequality.

These risks of market distortions should be considered in deciding whether to pursue, and how to design, equal ownership policies. However, in some ways the risks and limits of equal ownership reflect those of capitalism. The idea of capitalism is based on the notion that corporations should be able to raise capital from a diffuse range of investors. These investors naturally have different preferences and views, and they increasingly want corporations to consider them. As discussed above, information technologies significantly lessen the costs of

collecting and synthesizing dispersed retail interests.[160] Thus, we believe this risk is unlikely to materially increase the inherent risks of robust capital markets, and that capital markets will prove dynamic enough to adapt.

D. Encouraging Noise Trading

Broadening the ownership base of corporations may also lead to introducing a great deal of noise to stock markets. The concern is that lower-income individuals may be uninformed and unsophisticated, and therefore will act primarily as noise traders. The efficiency of capital markets depends on the presence of informed traders that gather and analyze market and firm specific information.[161] Noise traders, on the other hand, are those that falsely believe they have valuable informational advantage or superior ability to trade stocks.[162] The more noise traders there are, the more likely it is that stocks will deviate from their fundamental value. While noise traders can cancel each other, when they act as a herd, they may bias stock prices for a prolonged time. In the long run, such traders inevitably lose to more sophisticated traders when prices go back to their fundamental value.

However, middle- and low-income individuals would not necessarily act as noise traders. As discussed above, the evidence suggests that retail traders, who are likely less affluent than other shareholders, are often well-informed and engaged in corporate voting.[163] In any event, there is scope for complementing our proposal with programs to increase and improve financial literacy in order to encourage the new group of stock traders to engage in informed trading.[164] Finally, we do not require that the new class of equal ownership shareholders would hold stocks directly as retail investors. Rather they could hold it through sophisticated institutional investors that have a duty to take their viewpoints into account when voting their stocks.[165]

E. Regulatory Laxity

Equal ownership could create a convenient political environment to justify regulatory laxity in areas such as antitrust and labor law. Consumers and workers may incorrectly believe that they are overall benefitting from monopoly prices and low wages because they are shareholders. Thus, they may exert insufficient democratic pressure on authorities to effect policies, such as antitrust and consumer protection, that are important for total welfare and the distribution of wealth. But if the ownership share is too small, the profits that consumers and workers gain from equal ownership may be lower than the resulting harm from laxer regulation.[166]

[165] See text *supra* note 119–142.

[166] If consumers have a fraction of the shares, only a fraction of every dollar in increased monopoly price paid by a low-income consumer will return to consumer-owners in ownership value.

While these political influences would be harmful if they materialized, it is only a speculative possibility. It is impossible to predict how equal ownership would affect the legislative and regulatory process, and our proposal will inevitably require a great deal of experimentation. As we emphasized above, equal ownership is not a substitute to existing regulation, but rather a complement to address persistent concerns such as rising mark-ups and stagnant wages.

CONCLUSION

We have identified an alarming trend in the distribution of corporate ownership. For years, ownership has trended toward wealthier households owning an ever-larger share of public corporations. This trend is particularly concerning when considering the gradual increase in industry concentration and corporate profits, higher prices charged to consumers, and lower wages for workers. The inescapable conclusion is that low- and middle-income individuals are increasingly getting a lower share of the wealth created by corporations.

While policymakers and academics have been studying potential links between institutional ownership and market power, they have given insufficient focus to a potentially bigger problem: the declining ownership stake of ordinary people who are the true victims of market power. The literature on how to address market power has missed the potential upsides of broadening ownership as a policy tool to combat market power. Likewise, the corporate governance literature has failed to fully theorize the potential impact that corporate stakeholders can have on firm decisions and strategy if they had a greater ownership stake in corporations.

Because existing proposals to either break up large companies or regulate them like utilities have considerable political and practical limits, it is worth considering how equal ownership may accomplish similar goals. Expanding ownership would reduce the harms by giving back some of the value extracted to consumers and workers. To the extent that managers internalize owners' interests, more equal ownership could also push firms to adopt behavior that mimic firm behavior in a perfectly competitive market.

These insights indicate that the socio-economic distribution of ownership should be an integral part of the considerable intellectual energy devoted to figuring out how to improve markets. At a minimum, policies should be adopted to reverse the declining share of stakeholders in corporate ownership. Rather than focusing solely on antitrust and regulation, policymakers should consider the potentially powerful contribution of equal ownership in mitigating the costs of market power and perhaps even creating an alternative path to perfect competition in maximizing social welfare in the economy.

APPENDIX

A. The Distributional Effects of Equal Ownership

Consider a simple Cournot oligopoly market in which there are two firms, each producing the same product. The demand function is a function of the quantity of the product, and we assume that $P(Q) = 100 - Q$, where $Q = q_1 + q_2$, and q_1 and q_2 are the quantities produced by firms 1 and 2, respectively. The cost function is $C(q) = 40q$. Each firm $i = \{1,2\}$ chooses the quantity produced to maximize the following function:

$$Max_{q_i}\, \pi_i = P(Q)q_i - C(q_i) = (100 - Q)q_i - 40q_i.$$

We refer to the results under the Cournot oligopoly using the subscript *co*, and the results under perfect competition with the subscript *pc*. The first order condition yields: $q_1^{co} = (60 - q_2^{co})/2$ and likewise $q_2^{co} = (60 - q_1^{co})/2$. Solving this system of equations, we obtain $q_1^{co} = q_2^{co} = 20$, and $p^{co} = 60$. The consumer surplus (CS) is the triangle below the demand function and above the price charged in equilibrium. Thus, $CS^{co} = \frac{(100-p^{co})Q}{2} = \frac{(q_1^{co}+q_2^{co})^2}{2}$, which equals 800. The total welfare (TW) gains in the economy equal the profits of the firms and the consumer surplus. Thus, $TW^{co} = \pi_1^{co} + \pi_2^{co} + CS^{co}$ equals 1,600 (because $\pi_1^{co} = \pi_2^{co} = 400$).

Contrast this with a world in which there is perfect competition. In such a world, the price equals marginal costs, and the profits of firms equal zero. Thus, $p^{pc} = 40$, and $Q^{pc} = 60$. In this case, the firm does not make any profits, and TW^{pc}=CS^{pc}=1,800. From a social welfare perspective, this is a better outcome. The deadweight loss of the Cournot oligopoly is the difference between total welfare under perfect competition (which is equal to the consumer surplus since firms' profits are zero) and the welfare under a Cournot model (the consumer surplus plus the firms' profits), which in this case equals $1{,}800 - 1{,}600 = 200$.

Suppose now that in equilibrium where the firms are choosing quantity, the consumers receive a share, $s = [0,1]$, of both firms' profits. Consumers' welfare may be higher if they get to share in firms' profits. The higher their share of the profits, the higher consumer welfare would be. In this case, s($\pi_1^{co} + \pi_2^{co}$) is consumers' share of both firms' profits. Consumer welfare (CW) includes the consumer surplus plus their share of the profits of the two firms. Thus, $CW^{co} = CS^{co}$+s($\pi_1^{co} + \pi_2^{co}$). For example, for $s = 1/2, CW = 1{,}200$. Thus, giving a share of the ownership to consumers naturally distributes some of the gains from shareholders to consumers.

We note that in this case even if $s = 1$, the largest share the consumer can get in the company, they will still be worse off than in a world of perfect competition because their total welfare will be equal to 1,600. As we show below, this changes if the firms internalize the interests of consumers in choosing the quantity they produce.

B. The Governance Effects of Equal Ownership

We now assume that the firm is maximizing the interests of its owners as a whole, taking into account that some of its owners are also consumers. Therefore, the firm may increase quantity even if it has the effect of reducing the firm's profit because it knows that some of its owners will benefit as consumers from the price reduction and greater availability of products. The objective function of the firm is:

$$Max_{q_i}\, \emptyset_i = (1-s)\pi_i + s(\pi_i + CS),$$

subject to the constraint that $\pi_i \geq 0$. That is, the firm will not choose a quantity that renders it insolvent. Thus, $\emptyset_i = (1-s)[(100-Q)q_i - 40q_i] + s[(100-Q)q_i - 40q_i + Q^2/2]$ $= (100 - q_1 - q_2)q_i - 40q_i + (s(q_1+q_2)^2)/2$. This yields the following first order condition: $q_1^{co} = \frac{(s-1)q_2^{co}+60}{2-s}$, and $q_2^{co} = \frac{(s-1)q_1^{co}+60}{2-s}$. Thus, the quantity is clearly increasing in *s*, and therefore the price is decreasing in *s*.

The simplest way to show the result is to examine the equilibrium quantity, price, and welfare analysis for different levels of s. As shown in Figure 2, the optimal result, from a social welfare perspective, occurs when $s = 1/2$ and firms' profits are equal to zero. In this case, the price is 40 and each firm produces 30 units of product. This is equivalent to a world with perfect competition, where price equals marginal costs. The total welfare here equals 1,800, exactly the same as in a world with perfect competition.

If we increase s above 1/2, the output and prices stay the same as in the case where $s = 1/2$ because the firm is subject to the constraint that it must make nonnegative profits. Because $p^{co} = 30$, $Q^{co} = 60$, and $\pi_i^{co} = 0$ for $1 \geq s \geq \frac{1}{2}$, then the consumer surplus, consumer welfare, and total welfare stay the same as in the case where $s = 1/2$. The following table summarizes these dynamics in tabular form for different values of s.

Table 1: The Effect of Consumer Ownership on Welfare
